# Kneser's property for a semilinear parabolic partial differential equation with Dirichlet boundary condition

東北学院大学教養学部 上之郷高志 (Takashi Kaminogo)  
Department of Mathematics, Tohoku Gakuin University

**1. Introduction.** We consider an initial and boundary value problem

$$(E_n) \quad \begin{cases} \frac{\partial u}{\partial t} = \Delta u + F(t, x, u) & \text{for } 0 < t \leq T, x \in D, u \in \mathbf{R} \\ u(0, x) = u_0(x) & \text{for } x \in \overline{D}, \\ u(t, x) = 0 & \text{for } 0 < t \leq T, x \in \partial D, \end{cases}$$

where  $T > 0$  is a given constant,  $D = (0, 1)^n \subset \mathbf{R}^n$ ,  $F : [0, T] \times \overline{D} \times \mathbf{R} \rightarrow \mathbf{R}$  is continuous and  $u_0 \in C(\overline{D}, \mathbf{R})$  satisfies  $u_0(x) = 0$  on  $\partial D$ . A continuous function  $u(t, x)$  defined on  $[0, \tau] \times \overline{D}$  will be called a (*mild*) solution of  $(E_n)$  when  $u$  is expressed by

$$u(t, x) = \int_D G(t, x, y) u_0(y) dy + \int_0^t ds \int_D G(t-s, x, y) F(s, y, u(s, y)) dy,$$

where  $G$  is the *fundamental solution* of  $\partial u / \partial t = \Delta u$  with  $u = 0$  on  $\partial D$ .

We shall discuss the Kneser's property for solutions of  $(E_n)$ . In [2] and [3], we proved that solutions of  $(E_n)$  have Kneser's property, where the boundary condition is replaced with Neumann boundary condition and  $D$  is assumed to be a bounded domain with smooth boundary.

In this article, we always assume the following assumption (A) to the function  $F$ .

(A)  $F(t, x, y)$  is expressed by

$$F(t, x, u) = f(t, x, u) + g(t, x, u),$$

where  $f$  and  $g$  are continuous functions on  $[0, T] \times \overline{D} \times \mathbf{R}$  and satisfy

$$(1) \quad \begin{cases} f(t, x, u) = 0 & \text{for } 0 \leq t \leq T, x \in \partial D, u \in \mathbf{R}, \\ g(t, x, -u) = -g(t, x, u) & \text{for } 0 \leq t \leq T, x \in \overline{D}, u \in \mathbf{R}. \end{cases}$$

Only for simplicity of notations, we shall state our results in the case where  $n = 1$ , and hence,  $(E_n)$  will be reduced to the problem

$$(E_1) \quad \begin{cases} \frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + F(t, x, u) & \text{for } 0 < t \leq T, x \in \overline{D} = [0, 1], u \in \mathbf{R}, \\ u(0, x) = u_0(x) & \text{for } x \in \overline{D} = [0, 1], \\ u(t, 0) = u(t, 1) = 0 & \text{for } 0 < t \leq T, \end{cases}$$

where  $u_0$  is a continuous function satisfying  $u_0(0) = u_0(1) = 0$ . The following example shows that solutions of  $(E_1)$  are not always unique.

**Example.** Consider the following problem for  $t > 0, x \in [0, 1]$  and  $u \in \mathbf{R}$ .

$$(E) \quad \begin{cases} \frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + \sqrt{\frac{x^4 - 2x^3 + x}{12}} \sqrt{|u|} + \frac{12u}{1 + x - x^2}, \\ u(0, x) = 0, \\ u(t, 0) = u(t, 1) = 0. \end{cases}$$

It is clear that  $(E)$  admits the zero solution  $u(t, x) \equiv 0$ . Furthermore, it is not difficult to see that

$$u(t, x) = \frac{t^2(x^2 - x)(x^2 - x - 1)}{48} = \frac{t^2}{4} \cdot \frac{x^4 - 2x^3 + x}{12}$$

is also a solution of  $(E)$ .

**Remark.** The function  $F$  in  $(E)$  satisfies assumption  $(A)$ .

**2. Compactness of solutions.** It is well known (e.g. [1]) that the fundamental solution  $G$  for  $\partial u / \partial t = \partial^2 u / \partial x^2$  with  $u(t, 0) = u(t, 1) = 0$  is expressed by

$$(2) \quad G(t, x, y) = \sum_{k=-\infty}^{k=\infty} \{E(t, x - y + 2k) - E(t, x + y + 2k)\},$$

where  $E(t, \xi) = (4\pi t)^{-1/2} \exp(-\xi^2/4t)$  for  $t > 0, \xi \in \mathbf{R}$ .

Let  $X$  be any metric space. We shall denote by  $BC(X, \mathbf{R})$  the Banach space of all bounded and continuous functions on  $X$  with the norm  $\|\cdot\|$  defined by

$$(3) \quad \|v\| = \sup\{|v(x)|; x \in X\}$$

for  $v \in BC(X, \mathbf{R})$ . Similarly, for any compact metric space  $X$ , we shall denote by

$C(X, \mathbf{R})$  the Banach space of all continuous functions on  $X$  with the norm  $\|\cdot\|$  given by (3).

By assumption (A), the functions  $f$  and  $g$  admit a continuous and nondecreasing function  $\varphi : [0, \infty) \rightarrow (0, \infty)$  with the property that

$$(4) \quad |f(t, x, u)| \leq \varphi(|u|), \quad |g(t, x, u)| \leq \varphi(|u|)$$

for  $(t, x, u) \in [0, T] \times [0, 1] \times \mathbf{R}$ .

Now we shall define several extensions of the functions  $u_0(x)$ ,  $u(t, x)$ ,  $f(t, x, u)$  and  $g(t, x, u)$  in the following way. For a function  $u_0 \in C([0, 1], \mathbf{R})$  with  $u_0(0) = u_0(1) = 0$ , we can easily construct a continuous extension  $\hat{u}_0 : \mathbf{R} \rightarrow \mathbf{R}$  of  $u$  which satisfies that  $\hat{u}_0(x)$  is an odd mapping and is 2-periodic. Similarly, for  $\tau \in (0, T]$  and for a function  $u = u(t, x) \in C([0, \tau] \times [0, 1], \mathbf{R})$  satisfying  $u(t, 0) = u(t, 1) = 0$  on  $[0, \tau]$ , let  $\hat{u} = \hat{u}(t, x) \in C([0, \tau] \times \mathbf{R}, \mathbf{R})$  be a continuous extension of  $u$  which is an odd mapping and 2-periodic in  $x$  for each  $t \in [0, \tau]$ , while let  $\tilde{u} = \tilde{u}(t, x) \in C([0, \tau] \times \mathbf{R}, \mathbf{R})$  be a continuous extension of  $u$  which is an even mapping and 2-periodic in  $x$  for each  $t \in [0, \tau]$ . Finally, for the functions  $f$  and  $g$  satisfying (1), let  $\hat{f} = \hat{f}(t, x, u) \in C([0, T] \times \mathbf{R} \times \mathbf{R}, \mathbf{R})$  be an extension of  $f$  which is an odd mapping and 2-periodic in  $x$  for each  $(t, u) \in [0, T] \times \mathbf{R}$ , while  $\tilde{g} = \tilde{g}(t, x, u) \in C([0, T] \times \mathbf{R} \times \mathbf{R}, \mathbf{R})$  be an extension of  $g$  which is an even mapping and 2-periodic in  $x$  for each  $(t, u) \in [0, T] \times \mathbf{R}$ . Here, notice that  $\tilde{g}(t, x, u)$  is an odd mapping in  $u$  because of (1).

**Lemma 1.** For a function  $u_0 \in C([0, 1], \mathbf{R})$  with  $u_0(0) = u_0(1) = 0$ , we have

$$\int_D G(t, x, y) u_0(y) dy = \int_{\mathbf{R}} E(t, x - y) \hat{u}_0(y) dy.$$

**Proof.** It follows from (2) that

$$\begin{aligned} & \int_D G(t, x, y) u_0(y) dy \\ &= \sum_{k=-\infty}^{k=\infty} \left\{ \int_0^1 E(t, x - y + 2k) u_0(y) dy - \int_0^1 E(t, x + y + 2k) u_0(y) dy \right\} dy \\ &= \sum_{k=-\infty}^{k=\infty} \left\{ \int_{-2k}^{1-2k} E(t, x - z) u_0(z + 2k) dz + \int_{-2k}^{-1-2k} E(t, x - z) u_0(-z - 2k) dz \right\} dz \\ &= \sum_{k=-\infty}^{k=\infty} \left\{ \int_{-2k}^{1-2k} E(t, x - z) \hat{u}_0(z) dz + \int_{-1-2k}^{-2k} E(t, x - z) \hat{u}_0(z) dz \right\} dz \end{aligned}$$

$$= \int_{\mathbf{R}} E(t, x - y) \hat{u}_0(y) dy. \quad \square$$

**Lemma 2.** Suppose that (A) holds and that  $\tau \in (0, T]$ . Then for a function  $u \in C([0, \tau] \times [0, 1], \mathbf{R})$  satisfying  $u(t, 0) = u(t, 1) = 0$  for  $t \in [0, \tau]$ , it follows, for  $0 \leq s \leq t \leq \tau$ , that

$$\int_D G(t - s, x, y) f(s, y, u(s, y)) dy = \int_{\mathbf{R}} E(t - s, x - y) \hat{f}(s, y, \tilde{u}(s, y)) dy$$

and

$$\int_D G(t - s, x, y) g(s, y, u(s, y)) dy = \int_{\mathbf{R}} E(t - s, x - y) \tilde{g}(s, y, \hat{u}(s, y)) dy.$$

**Proof.** It is easy to observe that the following equalities hold for each  $(s, y) \in [0, \tau] \times \mathbf{R}$ .

$$\begin{aligned} \hat{f}(s, -y, \tilde{u}(s, -y)) &= -\hat{f}(s, y, \tilde{u}(s, y)), & \hat{f}(s, y + 2, \tilde{u}(s, y + 2)) &= \hat{f}(s, y, \tilde{u}(s, y)), \\ \tilde{g}(s, -y, \hat{u}(s, -y)) &= -\tilde{g}(s, y, \hat{u}(s, y)), & \tilde{g}(s, y + 2, \hat{u}(s, y + 2)) &= \tilde{g}(s, y, \hat{u}(s, y)). \end{aligned}$$

By using the similar arguments as in the proof of Lemma 1, we can easily prove the assertion of the lemma.  $\square$

Let  $h : [0, T] \times \mathbf{R} \times \mathbf{R} \rightarrow \mathbf{R}$  be a continuous function satisfying

$$(5) \quad |h(t, x, u)| \leq \varphi(|u|) \quad \text{for } (t, x, u) \in [0, T] \times \mathbf{R} \times \mathbf{R},$$

where  $\varphi : [0, \infty) \rightarrow (0, \infty)$  is a continuous and nondecreasing function introduced in the above. For this function  $h$ ,  $\tau \in (0, T]$  and for  $u \in BC([0, \tau] \times \mathbf{R}, \mathbf{R})$ , define a function  $H(h, u, \tau)$  on  $[0, \tau] \times \mathbf{R}$  by

$$[H(h, u, \tau)](t, x) = \int_0^t ds \int_{\mathbf{R}} E(t - s, x - y) h(s, y, u(s, y)) dy.$$

By using similar arguments as in the proof of Lemma 1.5 in [2], we can prove the following lemma.

**Lemma 3.** For any  $\tau \in (0, T]$ ,  $u \in BC([0, \tau] \times \mathbf{R}, \mathbf{R})$  and for any function  $h$  satisfying (5), we have

$$\begin{aligned} & |[H(h, u, \tau)](t, x) - [H(h, u, \tau)](t', x')| \\ & \leq 8M\sqrt{t}\sqrt{t' - t} + M(t' - t) + 2\sqrt{2}M\sqrt{t}|x - x'| \end{aligned}$$

for any  $0 \leq t < t' \leq \tau$  and  $x, x' \in \mathbf{R}$ , where  $M = \sup\{|h(t, x, u(t, x))|; t \in [0, \tau], x \in \mathbf{R}\} \leq \varphi(\|u\|) < \infty$ .

**Theorem 1 (Existence).** Suppose that (A) holds. Then for any function  $u_0 \in C([0, 1], \mathbf{R})$  with  $u_0(0) = u_0(1) = 0$ , there exists at least one solution  $u(t, x)$  of  $(E_1)$  on  $[0, \tau] \times [0, 1]$  for some  $\tau > 0$ .

**Proof.** Put  $\|u_0\| = M_0$  and take a number  $L$  satisfying  $L > M_0$ . Then we can choose a number  $\tau > 0$  so that an inequality

$$M_0 + 2\varphi(L)\tau \leq L$$

holds. We denote by  $V$  the set of all functions  $u \in C([0, \tau] \times [0, 1], \mathbf{R})$  which satisfy that  $\|u\| \leq L$ ,  $u(t, 0) = u(t, 1) = 0$  and that  $u(0, x) = u_0(x)$  for  $x \in [0, 1]$ . Then  $V$  is a closed and convex subset of  $C([0, \tau] \times [0, 1], \mathbf{R})$ . For every  $v \in V$ , we define a mapping  $\Psi v : [0, \tau] \times [0, 1] \rightarrow \mathbf{R}$  by  $[\Psi v](0, x) = u_0(x)$  for  $x \in [0, 1]$  and

$$[\Psi v](t, x) = \int_D G(t, x, y) u_0(y) dy + \int_0^t ds \int_D G(t-s, x, y) F(s, y, v(s, y)) dy$$

for  $0 < t \leq \tau$ ,  $x \in [0, 1]$ . Then  $\Psi v$  belongs to  $C([0, \tau] \times [0, 1], \mathbf{R})$  and  $[\Psi v](t, 0) = [\Psi v](t, 1) = 0$  for  $t \in (0, \tau]$ . It follows from Lemmas 1 and 2 that

$$\begin{aligned} (6) \quad [\Psi v](t, x) &= \int_{\mathbf{R}} E(t, x-y) \hat{u}_0(y) dy \\ &\quad + \int_0^t ds \int_{\mathbf{R}} E(t-s, x-y) \hat{f}(s, y, \tilde{v}(s, y)) dy \\ &\quad + \int_0^t ds \int_{\mathbf{R}} E(t-s, x-y) \tilde{g}(s, y, \hat{v}(s, y)) dy, \end{aligned}$$

thus we have

$$\begin{aligned} |[\Psi v](t, x)| &\leq M_0 + \int_0^t ds \int_{\mathbf{R}} E(t-s, x-y) \varphi(\|\tilde{v}\|) dy \\ &\quad + \int_0^t ds \int_{\mathbf{R}} E(t-s, x-y) \varphi(\|\hat{v}\|) dy \\ &\leq M_0 + 2\varphi(L)\tau \leq L \end{aligned}$$

because  $\int_{\mathbf{R}} E(t, x-y) dy = 1$ . Therefore, we obtain that  $\Psi(V) \subset V$ . It follows from (6) and Lemma 3 that  $\Psi(V)$  is relatively compact, and hence, we can find a fixed point  $u$  in  $V$  by Schauder's fixed point theorem. Clearly,  $u$  is a solution of  $(E_1)$ , which completes the proof.  $\square$

**Lemma 4.** Suppose that (A) holds. Then there exist two numbers  $\tau > 0$  and  $M > 0$  such that every solution  $u$  of  $(E_1)$  exists and satisfies  $|u(t, x)| \leq M$  on  $[0, \tau] \times [0, 1]$ .

**Proof.** Put  $\|u_0\| = M_0$ . Then any solution  $u$  of  $(E_1)$  satisfies

$$\begin{aligned} |u(t, x)| &\leq M_0 + 2 \int_0^t ds \int_{\mathbf{R}} E(t-s, x-y) \varphi(\|u(s)\|) dy \\ &\leq M_0 + 2 \int_0^t \varphi(\|u(s)\|) ds \end{aligned}$$

for  $t > 0$  and  $x \in [0, 1]$  as long as  $u$  exists, where  $\|u(s)\| = \sup\{|u(s, y)|; y \in [0, 1]\}$ . Therefore, it follows that

$$\|u(t)\| \leq M_0 + 2 \int_0^t \varphi(\|u(s)\|) ds.$$

If we put  $v(t) := \|u(t)\|$  and  $w(t) := M_0 + 2 \int_0^t \varphi(v(s)) ds$  for  $t > 0$ , then we have  $v(t) \leq w(t)$  and  $w'(t) = 2\varphi(v(t)) \leq 2\varphi(w(t))$ . By the comparison theorem in the theory of ordinary differential equations, the maximal solution  $p(t)$  of  $p' = 2\varphi(p)$  with  $p(0) = M_0$  exists on  $[0, \tau]$  for some  $\tau > 0$  and an inequality  $p(\tau) \geq p(t) \geq w(t)$  holds on  $[0, \tau]$ . By putting  $M = p(\tau)$ , we have the assertion.  $\square$

**3. Kneser's property.** For the functions  $f$  and  $g$  satisfying (1) and for  $m \in \mathbf{N}$ , we put

$$f_m(t, x, u) = \frac{m}{2} \int_{u-\frac{1}{m}}^{u+\frac{1}{m}} f(t, x, v) dv, \quad g_m(t, x, u) = \frac{m}{2} \int_{u-\frac{1}{m}}^{u+\frac{1}{m}} g(t, x, v) dv.$$

Then  $f_m(t, x, u) = 0$  for  $x = 0, 1$ , while  $g_m(t, x, -u) = -g_m(t, x, u)$  by virtue of (1). It is easy to see that  $\{f_m\}$  and  $\{g_m\}$  converge, respectively, to  $f$  and  $g$  uniformly on every compact set in  $[0, T] \times [0, 1] \times \mathbf{R}$ . Clearly,  $f_m$  and  $g_m$  are locally Lipschitz continuous in  $u$ . Moreover, by the mean value theorem in integration, we have

$$\begin{aligned} |f_m(t, x, u)| &\leq \frac{m}{2} \int_{u-\frac{1}{m}}^{u+\frac{1}{m}} |f(t, x, v)| dv \leq \frac{m}{2} \int_{u-\frac{1}{m}}^{u+\frac{1}{m}} \varphi(|v|) dv \\ &= \varphi(|u + \theta/m|) \leq \varphi(|u| + 1), \end{aligned}$$

where  $\theta$  is a suitable number satisfying  $-1 < \theta < 1$ . By replacing  $\varphi(s+1)$  by  $\varphi(s)$ , we may assume that  $|f_m(t, x, u)| \leq \varphi(|u|)$ . Similarly, we may also assume that  $|g_m(t, x, u)| \leq \varphi(|u|)$ .

**Theorem 2.** Suppose that (A) holds and that  $u_0 \in C([0, 1], \mathbf{R})$  is an arbitrary function satisfying  $u_0(0) = u_0(1) = 0$ . Then a family

$$\mathcal{F} = \{u \in C([0, \tau] \times [0, 1], \mathbf{R}); u \text{ is a solution of } (E_1)\}$$

is compact and connected in  $C([0, \tau] \times [0, 1], \mathbf{R})$  when  $\tau > 0$  is sufficiently small.

**Proof.** By Lemma 4, there exist  $\tau > 0$  and  $M > 0$  such that every solution  $u$  of  $(E_1)$  exists and satisfies  $|u(t, x)| \leq M$  on  $[0, \tau] \times [0, 1]$ . For this  $\tau > 0$ , we shall prove the assertion of the theorem.

It suffices to show that  $\mathcal{F}$  is connected because the compactness of  $\mathcal{F}$  is obvious by Lemma 3. Suppose that  $\mathcal{F}$  is not connected. Then there exist an open set  $\mathcal{O}$  and two nonempty compact sets  $\mathcal{F}_1$  and  $\mathcal{F}_2$  in  $C([0, \tau] \times [0, 1], \mathbf{R})$  such that

$$\mathcal{F}_1 \cup \mathcal{F}_2 = \mathcal{F}, \quad \mathcal{F}_1 \subset \mathcal{O}, \quad \mathcal{F}_2 \cap \overline{\mathcal{O}} = \emptyset.$$

Let  $u_1$  and  $u_2$  be any elements in  $\mathcal{F}_1$  and  $\mathcal{F}_2$ , respectively. Then, for each  $m \in \mathbf{N}$ ,  $u_i$  is a solution of

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + H_i(t, x, u), \quad (i = 1, 2),$$

where

$$H_i(t, x, u) = F(t, x, u_i(t, x)) - F_m(t, x, u_i(t, x)) + F_m(t, x, u)$$

and

$$F_m(t, x, u) = f_m(t, x, u) + g_m(t, x, u).$$

Let  $m$  be fixed. For any  $\theta \in [0, 1]$ , define  $\Phi_\theta(t, x, u)$  by

$$\Phi_\theta(t, x, u) = (1 - \theta)H_1(t, x, u) + \theta H_2(t, x, u).$$

Then  $\Phi_\theta(t, x, u)$  is expressed by

$$\Phi_\theta(t, x, u) = G_m(t, x) + f_m(t, x, u) + g_m(t, x, u),$$

where

$$\begin{aligned} G_m(t, x) = & (1 - \theta)\{F(t, x, u_1(t, x)) - F_m(t, x, u_1(t, x))\} \\ & + \theta\{F(t, x, u_2(t, x)) - F_m(t, x, u_2(t, x))\}. \end{aligned}$$

Here, we notice that  $G_m(t, 0) = G_m(t, 1) = 0$ . Since  $\{G_m(t, x)\}$  converges to 0 uniformly on  $[0, \tau] \times [0, 1]$  as  $m \rightarrow \infty$ , we may assume that  $|G_m(t, x)| \leq 1$  for  $m \in \mathbf{N}$

by taking a subsequence if necessary. Therefore, we may also assume that

$$|G_m(t, x) + f_m(t, x, u)| \leq \varphi(|u|)$$

by replacing  $1 + \varphi(s)$  by  $\varphi(s)$ .

For any fixed  $m \in \mathbf{N}$ , a problem

$$(E_\theta) \quad \begin{cases} \frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + \Phi_\theta(t, x, u) & \text{for } 0 < t \leq \tau, x \in [0, 1], u \in \mathbf{R}, \\ u(0, x) = u_0(x) & \text{for } x \in [0, 1], \\ u(t, 0) = u(t, 1) = 0 & \text{for } 0 < t \leq \tau \end{cases}$$

has a unique solution  $v_\theta(t, x)$  because  $\Phi_\theta(t, x, u)$  is locally Lipschitz continuous in  $u$ . Evidently,  $v_0 = u_1$  and  $v_1 = u_2$ . Moreover, it is not difficult to verify that a mapping  $\theta \mapsto v_\theta$  is continuous from  $[0, 1]$  into  $C([0, \tau] \times [0, 1], \mathbf{R})$ , and hence, there exists a  $\theta \in [0, 1]$  such that  $v_\theta \in \partial\mathcal{O}$ . We denote these  $\theta$  and  $v_\theta$  by  $\theta_m$  and  $u_m$ , respectively. Then  $u_m$  is a solution of  $(E_{\theta_m})$  and a relation  $u_m \in \partial\mathcal{O}$  holds. It follows from Lemma 3 that  $\{u_m\}$  is equicontinuous on  $[0, \tau] \times [0, 1]$ , and hence, we may assume that  $\{u_m\}$  converges uniformly to some  $u \in C([0, \tau] \times [0, 1], \mathbf{R})$  by taking a subsequence if necessary. Since  $\{\Phi_{\theta_m}\}$  converges to  $f + g$  uniformly on every compact set in  $[0, \tau] \times [0, 1] \times \mathbf{R}$ ,  $u$  is a solution of  $(E_1)$ , which implies that  $u \in \partial\mathcal{O}$  and  $u \in \mathcal{F}$ . This is a contradiction.  $\square$

The following corollary is a direct consequence of Theorem 2.

**Corollary.** Under the same assumptions as in Theorem 2, a set

$$\mathbf{F} = \{u(\tau) \in C([0, 1], \mathbf{R}); u \text{ is a solution of } (E_1)\}$$

is compact and connected in  $C([0, 1], \mathbf{R})$  when  $\tau > 0$  is sufficiently small.
